Instructions:

My program uses Meteor.js as the web framework for this assignment. React.js is used for the UI and Mongo DB is used for the backend.

To use this program in the Linux labs, Meteor needs to be installed with all dependencies added and can be found in the package.json file. Once all is good, all that is needed is to go inside the directory and run "Meteor" which will start up the program and can be accessed from ://localhost:3000.

Finally, to get unique users for this program it has to be from different browsers. I've used Safari, Firebox, Chrome, Opera and Internet Explorer/Microsoft Edge to get at least five users. So, you would need to have all five browsers installed to play with five users.
